[P-A] Polking & Arnold, ODEs using MATLAB, 3rd Ed

A. Getting Started with MATLAB

Read Chapters 1 and 3 in Polking. Do this before trying to go on.

B. More on Functions

Once a function $y=g(x)$ is defined with a M-file you now know how to graph it on an interval $[a,b]$ using the plot command. First you partition $[a,b]$. Next you evaluate g at these values. The plot command then plots these vertices connecting them by lines to give a piecewise linear approximation to the graph of g .

Example: Plot $\sin(x^2)$ on $[-1,4]$. First we make an M-file.

```
*****  
function y=g(x)  
y=sin(x.^2);  
*****
```

Go to the command window and type:

```
*****  
x=-1:.1:4;  
plot(x,g(x))  
title('y=sin(x^2)')  
*****
```

Note $x=[-1, -.9, \dots, 3.9, 4]$ and $g(x)=[g(-1), g(-.9), \dots, g(3.9), g(4)]$. The graph is pretty crude because g oscillates more as x increases. A second way to graph is with the command fplot.

Example: (continued)

Go to the command window and type:

```
*****  
fplot('g(x)', [-1,4])  
*****
```

One of the conveniences of fplot is, given g.m, it determines how fine the partition of $[a,b]$ needs to be (what the vector x should

be) so that the piecewise linear approximation gives an accurate picture. A second feature of fplot is that it does not require g.m to be written with array smart notation as is required when using plot.

CAUTION!! Don't name a function y(x) (that is, use the file y.m); fplot will not plot it. Also fplot only recognizes "x" as the independent variable. So type "fplot('g(x)',[-1,4])", not "fplot('g(t)',[-1,4])" even if you used "t" as the independent variable in g.m.

ASSIGNMENT 1:

$$A. \text{ a) Let } A = \begin{bmatrix} 1 & 7 \\ 0 & -3 \end{bmatrix} \quad B = \begin{bmatrix} -3 & 2 \\ 3 & -2 \end{bmatrix} \quad C = \begin{bmatrix} 3 & 4 & 1 \\ -2 & -1 & 4 \\ 0 & -4 & 3 \end{bmatrix}$$

$$v = [3 \ 5]' \quad w = [2 \ -9]' \quad x = [-4 \ 3] \quad y = [0 \ 6 \ -3].$$

Note $[\]'$ is the transpose of $[\]$.

Try to find the following combinations in MATLAB. Which are defined and which are not? Where a combination is not defined explain why.

$$A*A \quad A*B \quad A*C \quad A.*A \quad A+B \quad A+C \quad A./C \quad A.\backslash B$$

$$A*x \quad x*A \quad v*A \quad x.*A \quad A.*x \quad y*C \quad C*x \quad C*y$$

$$A*v \quad y.^2 \quad y^2 \quad A^2 \quad x+y \quad v*w \quad x*w \quad x.*w$$

b) Show that $A = \begin{bmatrix} 1 & -2 \\ 0 & 3 \end{bmatrix}$ and $B = \begin{bmatrix} -2 & -3 \\ 0 & 1 \end{bmatrix}$ commute.

c) Consider the initial value problem

$$\begin{aligned} z'(x) + 4z(x) &= 0 \\ z(0) &= 1 \\ z'(0) &= -2. \end{aligned}$$

From Section 5.2 in [B-D] we have a power series representation for z(x):

$$z = a_0 + a_1 x + a_2 x^2 + \dots$$

where $a_0 = z(0) = 1$ and $a_1 = z'(0) = -2$.

From Math 262 you can solve the i.v.p. exactly: $z = \cos(2x) - \sin(2x)$ (for a review of this see Chapter 3 in [B-D]).

First find a_2 and a_3 . Then make M.files for the three functions

$$z_2(x) = a_0 + a_1 x + a_2 x.^2,$$

$$z_3(x) = a_0 + a_1 x + a_2 x.^2 + a_3 x.^3, \text{ and}$$

$$z(x) = \cos(2x) - \sin(2x) \text{ for } x \text{ in } [0, \pi/2].$$

Plot the three curves on the same figure. Use different line styles for each curve, and label the figure appropriately.

B. Graph $f(x) = \cos(x.^4)$ on $[0, 2]$.

a) Use the plot command with subintervals of length $h = .2$.

b) Use fplot.

FOR ALL OF YOUR MATLAB GRAPHING HOMEWORK FOR THIS COURSE TITLE YOUR GRAPHS.
