

Math 495QC
Quantum Computing
Fall 2025
Ralph M. Kaufmann

Course description:

This course will be an introduction to the theory underlying quantum computing and topological quantum computing for undergraduates. The course is designed to be self-contained. We will start with the basics of Boolean logic, linear algebra and the axioms and foundations of quantum mechanics. We will then go into spins, unitary matrices and quantum gates. As an application, we will discuss algorithms, such as Shor's algorithm and RSA encryption. We expect to cover topological quantum computing using anyons and if time permits further topics. This gives a solid background for work in this field.

The course is open to anyone in mathematics, physics, computer science, chemistry, science or engineering. A good working understanding of linear algebra will be useful. The pace of the course will be adjusted to the audience.

The basic outline is as follows:

1. Boolean logic
2. Linear algebra
 1. Complex vector spaces
 2. Hilbert spaces
 3. Tensor products
3. Quantum mechanics
 1. Axioms
 2. Bloch sphere
 3. Spin systems
4. Quantum gates
 1. Universal gate sets
 2. Shor's algorithm
 3. RSA
5. Topological quantum computing
 1. Linear algebra II. Unitary representations
 2. Spin coupling (Clebsch Gordan coefficients).
 3. Anyon theory
6. Additional topics (depending on time and the audience)
 1. Lattices and Toric code
 2. Quantum error correction
 3. Programming existing systems

The course will have its own script.
